

Based on the available data, February 1st and March 1st do not show up as unusually high-revenue days; where we do see spikes on those dates in product-level data, they are driven by selling more of the usual high-value lesson packs and practice-credit bundles at normal prices, not by different pricing or a different coach mix.

Supporting findings

- In the main daily revenue views, almost every day in the period – including February 1st and March 1st – shows total revenue of 0.0, so those dates cannot be statistically identified as outliers versus other days in that series.

- Where transaction-level detail is visible for 2025-02-01 and 2025-03-01, revenue on those dates is dominated by high-value Experience products: multi-lesson packs (10-, 20-, 50-lesson packs for named coaches) and practice-credit bundles (10, 25, 50 credits, 30/60-minute practice credits), with F&B and ancillary services contributing only marginally.

- The same lesson packs and practice bundles that dominate February 1st and March 1st are also the main revenue drivers on typical days, indicating that the spike pattern is essentially a scaled-up version of the normal product mix rather than a shift into a different category such as one-off events or F&B. - For these key products, unit economics appear stable: implied prices for 10-lesson packs (around 981), 50-lesson packs (around 4,360), and practice credits match baseline levels, so higher revenue on February 1st and March 1st is explained by more units sold, not higher prices or larger per-unit packages. - Client-level revenue is structurally heavy-tailed across the dataset, with a small number of high-spend clients and many low-spend clients; February 1st and March 1st do

feature some very large client transactions, but the overall pattern of concentration looks broadly similar to non-target days rather than uniquely extreme.

- Coach-level revenue patterns on February 1st and March 1st mirror the usual hierarchy: the same high-revenue coach and service combinations (notably practice and leading lesson coaches such as Johnson Poh, Joey Poh, Jiali Khee, Lim Jihyeon, Jasper Park, Kim On You, and others) dominate both on those dates and across the broader period, suggesting the spike is driven by higher throughput of the usual coaches rather than a different or more premium coach mix.

Recommendations

- Validate and fix the daily revenue aggregation so that February 1st and March 1st in the daily view reconcile to the underlying transaction-level data; without a consistent daily series, it is impossible to reliably identify or

size revenue spikes.

- Once the daily series is corrected, explicitly benchmark all first-of-month dates against other days to see whether there is a recurring uplift pattern (for example, from membership renewals or scheduled package purchases) that you can plan around for staffing and marketing.
- Design targeted first-of-month campaigns around high-value lesson packs and practice-credit bundles, since these products already drive the observed spikes; for example, pre-scheduled renewals, limited-time add-on credits, or bundled offers with named coaches.
- Monitor a simple set of operational KPIs on high-revenue days – units of lesson packs sold, units of practice credits sold, and number of high-spend clients – so you can distinguish volume-driven spikes from one-off large client purchases and adjust capacity accordingly.
- Introduce basic client-concentration tracking (e.g., top-5 and top-10 client share by day) so that when you see a spike on dates like February 1st and March 1st, you can quickly tell whether it is broad-based demand or dependence on a few large buyers.

Caveats

- Interpreted “full available history up to 2026-05-03” as full_history (2023-01-01 to 2026-05-03), based on anchor=analysis_run_date (2026-05-03).
- There is a fundamental inconsistency between daily-level tables that show zero revenue on all days and product-level tables that show substantial non-zero revenue on February 1st and March 1st; any conclusions about outlier status or calendar patterns should be revisited once this data issue is resolved.
- Because the first-of-month and weekday comparison views could not be reliably constructed, we cannot confirm whether February 1st and March 1st are part of a systematic first-of-month or calendar-driven uplift versus being isolated spikes.
- The decomposition of revenue into quantity versus unit-price effects is based on observed stability of implied prices rather than a full formal breakdown, so the exact percentage of the spike attributable to volume versus pricing cannot be quantified from the current data.
